DAILY TASK

Dockerizing the Donation Management API

> **Objective:** Update your previously developed Donation Management System API to run seamlessly inside a Docker container environment alongside its database engine.

TASK REQUIREMENTS

1. Create a `Dockerfile` to build and run your ASP.NET Core API inside a Docker container.
2. Create a `compose.yaml` file to run the API and its database together using Docker Compose.
3. Configure the database connection parameters using environment variables rather than hardcoded credentials.
4. Ensure the API can connect to the database and execute successfully within the Docker container network.
5. Update your `README.md` with clear step-by-step instructions on how to build, start, and stop the application using Docker Compose.

REQUIRED DELIVERABLES

- `Dockerfile`
- `compose.yaml`
- `.dockerignore`
- Updated `README.md`

IMPORTANT GUIDELINES

- Use your existing Donation Management System project.
- Do not redesign the database schema or rewrite the API.
- Do not hardcode database credentials in your source code.

EXPECTED OUTCOME

Verification Target: Verify that both the API and database containers start, connect over the container network, and run successfully using Docker Compose without requiring local host dependencies.
